The Distribution of MVT-Related Metals in Ground Water of the Ozark Plateaus Region of the United States

By Lopaka Lee and Martin B. Goldhaber

Introduction

This report is a compilation of figures and tables that show the spatial and statistical distribution of dissolved elemental concentrations of As, Ba, Cd, Co, Cu, Cr, Mo, Ni, Pb, and Zn, in ground water from the Ozark Plateaus region of the United States.

This product is part of a USGS project that is focused on characterizing the effects of Mississippi Valley-type (MVT) mineralization on the background ground water chemistry of the Ozark Plateaus region of the United States (Lee, 2000). The first phase of this parent study involved the investigation of spatial and statistical relationships between MVT-related metals in rocks and groundwater. The figures and tables of this report are a product of this study phase and are centered on characterizing, on a regional level, the spatial and statistical distribution of MVT-related metals in aquifer rocks. A companion report that shows the spatial and statistical distribution of MVT-related metals in acid-insoluble residues of borehole rocks from the Ozark region has been published as a USGS open-file report under the title: *The distribution of MVT-related metals in acid-insoluble residues of Paleozoic rocks in the Ozark Plateaus region of the United States* (Lee and Goldhaber, 2001).

A minimal amount of scientific interpretations are provided within the text. A detailed interpretation of this data, as it relates to the effects of MVT mineralization on the natural-background ground water chemistry of the Ozark region, is currently available in Lee (2000).

Description of the Dataset

The figures and tables of this report are based on a database of 400 ground-water samples from 380 different locations distributed throughout the Ozark region (Figure 1). The entire ground-water dataset, along with instructions on how to obtain digital copies of records, is listed in Appendix A.

All ground-water samples used within this report were

generated during USGS Water-Resources Division (USGS-WRD) programs. Ground-water samples are from both springs and wells. A majority of these water samples are associated with the USGS National Water Quality Assessment (NAWQA) Program – Ozark Plateaus Study Unit (Freiwalder, 1991; Peterson, Adamski, and others, 1998). A smaller set of the USGS water data is from water-quality monitoring programs implemented by the USGS-WRD, but not directly associated with the NAWQA program. These samples were obtained by the same office and personnel executing the Ozark NAWQA study and were obtained and analyzed in accordance with standard USGS protocol (see USGS Technical Water Resources Investigations (TWRI) manuals available at (http://oregon.usgs.gov/pubs_dir/twri-list.html)).

All ground-water samples used in this report are full determinations of major elements and field parameters.

Data records for ground-water samples contain information on the principal water-bearing geologic formations of springs and wells, and also well construction information where relevant. Table 1 summarizes the statistical distribution of water samples by water-yielding formation (or geologic unit). The total percentage of groundwater samples representative of the individual aquifer units of the Ozark Aquifer System are: 36% from the Springfield Plateau aquifer unit, 64% from the Ozark aquifer unit, and 0% from the St. Francois aquifer unit. Groundwater samples from the St. Francois aquifer unit were not obtained for use in this report. This aquifer is of minor importance as a drinking water source in the Ozarks (Imes and Emmett, 1994).

Trace elements were determined in 200 ground-water samples (Table 1). The total percentage of groundwater samples with trace element data representative of individual aquifer units of the Ozark aquifer system are: 20% from the Springfield Plateau aquifer unit, and 80% from the Ozark aquifer unit. The lower detection limit for almost all trace metal analyses within the dataset is 1 ug/L. However, for some analyses, detection limits are as high as 6 ug/L. For mapping and plotting purposes, all concentrations of trace elements reported at the lower limits of detection were set to one-half of the reported detection limit.

2 The Distribution of MVT-Related Metals in Ground Water of the Ozark Plateaus Region of the United States

Table 1. Statistical distribution of ground-water samples by geologic formation and aquifer unit

Hydrologic Unit	Groundwater Analyses (with major ions)	Groundwater Analyses (with trace elements)
Western Int. Plains confining	0	0
Springfield Plateau aquifer	144	40
Ozark confining	0	0
Ozark aquifer	256	160
St. Francois confining	0	0
St. Francois aquifer	0	0
Basement confining	0	0
TOTAL	400	200

Maps of the Concentrations of Dissolved Metals in Ozark Region Ground Water

Figures 2 through 9 show the distribution of dissolved MVT metals in groundwater samples. Over most of the Ozark region, the observed concentrations of MVT-related metals are typically below 100 ug/L for Zn and below 1-5 ug/L for all other MVT metals. However, dissolved concentrations in excess of these limits consistently occur in the southwestern portion of the Ozark region. In this area, concentrations of MVT metals in groundwater are elevated with respect to regional concentrations. Dissolved Zn in this area occurs in concentrations up to 2000 ug/L (Figure 9). Dissolved As, Cd, Co, and Cr, exceed 1 ug/L (Figures 2 through 5). The highest concentrations of dissolved metals occur in a northwest-southeast striking trend that contains the Northern Arkansas mining district. This overall trend is coincident with the Chesapeake Tectonic Zone.

Figure 10 shows the geologic source of ground-water samples that contain at least one trace-metal that is elevated with regard to the typically observed concentrations. Elevated dissolved-metal concentrations in northern Arkansas are predominately associated with groundwater from the Everton Formation and Jefferson City-Cotter Dolomites. Other water samples in northern Arkansas with elevated dissolved metal concentrations are associated with wells producing from multiple formations in the upper Ozark aquifer unit. Figure 10 also shows some correlation with elevated metals and structural features such as fault traces and tectonic-zone trends. Elevated metals are observed in the Boone Formation, Jefferson City-Cotter Dolomite and Everton Formation, the Roubidoux-Gasconade Dolomites, and to a limited extent, the Eminence-Potosi Dolomites.

Appendix A: Tabular Listing of Chemical Analyses of Ground Water Samples

Table A1 lists the dataset used to generate the figures of this report. The listed data records do not contain all of the fields that are available within the USGS Watstore database for each record. Other analyses, not used in this study, may be available at individual sites. Digital copies of this dataset, that contain all available analyses and sample information, may be obtained on-line at <http://water.usgs.gov/owq/data.html>

Figures A1-A5 are provided as a means to identify individual sites and records. Data for individual sampling sites are obtained by using these figures, and their index numbers, to identify station ID numbers. The listed station ID numbers in table A1 are used to identify sites within the USGS Watstore database.
